

women, on younger skin they can confer somewhat of an opacity, so that the natural translucence of the young skin does not show through as effectively as would be desired.

There thus continues to be a need for a makeup that can reduce the appearance of lines and wrinkles on the skin, but at the same time will be lightweight, sheer, and translucent. Such a product will benefit both older and younger skins in the minimizing of surface flaws, yet at the same time, will permit the younger skin to retain its natural-looking glow. The present invention now provides such a product.

#### Summary of the Invention

The invention relates to a method of reducing the appearance of lines and wrinkles on the skin, which comprises applying to the skin a makeup composition comprising an interference pigment having a blue or violet reflectance, combined with at least one metal oxide pigment. The invention also relates to a makeup composition comprising an interference pigment having a blue or violet reflectance, at least one metal oxide pigment, and a non-spherical, non-matte inorganic powder. In a preferred embodiment, the inorganic powder is bismuth oxychloride.

#### Detailed Description of the Invention

It has been unexpectedly discovered that the presence of an interference pigment having a blue or violet reflectance in a standard makeup composition, particularly a foundation, can create the illusion of substantially flawless skin, by "deceiving" the observer's eyes into not perceiving the lines and wrinkles that are actually present on the wearer's skin. The human eye has different sensitivities to different wavelengths of light, and the blue-violet wavelengths are ones to which the eye is least sensitive. Surprisingly, the presence of corresponding colors of interference pigment has this effect on the eye when used in a makeup, in that when the makeup is applied to the face and receives light, it reflects that light back in such a way that the viewer does not see the wrinkles lying beneath it, but rather sees a smooth, unlined complexion. Interference pigments are defined as thin platelike layered particles having a high refractive index, which, at a certain thickness, produce interference colors, resulting from the interference of typically two, but occasionally more, light reflections, from different layers of the plate. The most

09482773-011300

common examples of interference pigments are micas layered with 50-500nm films of  $\text{TiO}_2$ ,  $\text{Fe}_2\text{O}_3$ , or  $\text{Cr}_2\text{O}_3$ , or combinations thereof. The interference pigment of the present invention produces a blue or violet color, at wavelength of about 380-490 nm, from the interference layer. The mica base may be colored or uncolored. Such pigments are not new, and have been previously used in cosmetics, primarily in very small quantities as a colorant in skin care products to confer a pearlescence to the product, or at high levels in makeup products such as eyeshadows, lipsticks or blushes, to confer a blue pearlescent color. They have also been previously used in makeup products, at relatively high levels, i.e., 10% or more, to disguise the appearance of major skin imperfections, such as hyperchromic pigmentation on the face, for example, port wine stains or hemangiomas. In the latter usage, unlike the present, the makeup composition containing the pigment is intended to complement the hyperchromic pigmentation, rather than match the normal color of the skin surface to which it is applied. Therefore, the previous known uses of these blue or violet pigments have neither been recognized nor exploited this unique property.

The blue or violet pigment is employed in the composition in an amount of about 1 to about 9%, preferably about 4 to about 8% by weight of the total composition. The blue or violet interference pigments of the invention are available commercially from a number of sources. The preferred blue or violet interference pigment is a titanated mica which is available, for example, from Rona under the tradename Timiron®, or from Engelhard under the tradename Flamenco®. The latter pigments have only a blue or violet reflectance color. However, the interference pigment used may also be one having not only a blue or violet reflectance, but also one or more other reflectance colors, by virtue of the presence of one or more additional interference layers, that may or may not be the traditional types of substrates. Examples of such interference pigments are available commercially from BASF under the tradename Sicopearl.®, the latter containing interference layers comprising silica, iron oxide, and optionally, aluminum. Additional such pigments are also available from Flex Products, Inc., under the tradename Chromaflair®.

In the makeup compositions of the invention, the blue or violet interference pigment is combined with at least one metal oxide pigment of the type ordinarily used in

color cosmetics, to give a "skin-colored" appearance to the formula. Examples of useful pigments include iron oxides (yellow, red, brown or black), titanium dioxide(white), zinc oxide, chrome oxide(green), chrome hydrate(green), ultramarines, manganese violet, ferric ferrocyanide, carmine 40, ferric ammonium ferrocyanide, or combinations thereof. Particularly preferred is a combination of one or more iron oxides with titanium dioxide. These pigments are typically present in an amount of about .1 to about 30%, preferably about 0.1 to about 20%.

Organic pigments may also optionally be included; these include natural colorants and synthetic monomeric and polymeric colorants. Exemplary are phthalocyanine blue and green pigment, diarylide yellow and orange pigments, and azo-type red and yellow pigments such as toluidine red, litho red, naphthol red and brown pigments. Also useful are lakes, which are pigments formed by the precipitation and absorption of organic dyes on an insoluble base, such as alumina, barium, or calcium hydrates. Particularly preferred lakes are primary FD&C or D&C Lakes and blends thereof. Stains, such as bromo dyes and fluorescein dyes can also be employed.

The composition also preferably contains an inorganic powder. It has been observed that, with the use of interference pigments producing only a blue or violet reflectance color in combination with metal oxides alone, these compositions do produce the desired reduction in appearance of fine lines and wrinkles, but it is an "all-or-nothing" appearance: the viewer perceives the full benefit of the reflectance from the interference pigment when looking at the skin from the specular angle, or head-on; however, when the same skin is viewed at an incident angle, the reflectance from the interference layer is not visible, and only the pigment is seen. Thus, the transition between these two views is quite sharp, and therefore somewhat less than ideal. However, it has been unexpectedly discovered that the transition between viewing at specular and incident angles can be softened by the inclusion in the formula of an inorganic powders, such as a silica or polymethylmethacrylate. Although the powder can be any of the type ordinarily used in cosmetics, it is particularly preferred that the powder be a non-matte powders, in an amount of about 2 to about 10%. The most preferred powders for this purpose are plate-like, non-spherical powders that confer some luster, but not an overt shine, so that there is still some reflectance, albeit muted, even

Methyl paraben	0.35
<u>Phase II</u>	
Stearth-21	0.50
<u>Phase III</u>

Phenoxyethanol	0.50

Phase I is mixed and heated to 45°C under propeller agitation. Phase II is added and mixed until uniform. Phase III is sprinkled in and mixing is continued. Phases I-III are the milled in a suitable milling machine (i.e.: colloid mill, ball mill, etc.) Milling is complete when no pigment particles are visible when the mixture is pressed between 2

glass slides. Phase IV is used to rinse out the mill. Phases V, VI, and VII are added to phases I-III under propeller type mixing, and until uniform. Phases I-VII are known as the "water phase". This is then heated to 75°C.

Phase VIII is heated in a suitable container to 80°C under similar propeller mixing. This is the "oil phase".

When both phases are at temperature, the oil phase is slowly added to the water phase. A drop in type-homogenizer is then inserted and the speed is set so as not to introduce air into the batch. The temperature is held between 75 and 80°C for 15 minutes then the batch is cooled to 25°C via propeller mixing.

Example 2. This example illustrates a formulation which is a water-in-oil emulsion of the present invention.
